#### Abstract

In this paper we prove a common fixed theorem in $G$-metric space using pairs of weakly compatible mappings.

Key Words: Complete G-metric space, weakly compatible mapping,

## INTRODUCTION

Banach contraction principle has been generalized in various spaces through different mappings. It has been a centre of rigorous research. After Gahler gave the concept of 2-metric space Dhage [2, 3] introduced the concept of D-metric space, but most of the results in D-metric space were proven invalid by Mustafa and Sims [14, 15]. They further introduced the concept of G-metric. Here we prove a common fixed point theorem in G-metric space, for six pairs of weakly compatible mappings.

## DEFINITIONS AND PRELIMINARIES

We here begin with some definitions and results for G- metric spaces that will be used in the following sections.
Definition 2.1: [15] Let $X$ be a nonempty set. and let G; $\mathrm{X} \times \mathrm{X} \times \mathrm{X}--->\mathrm{R}^{+}$be a function satisfying the following axioms
$\left(\mathrm{G}_{1}\right) \mathrm{G}(\mathrm{x}, \mathrm{y}, \mathrm{z})=0$ if $\mathrm{x}=\mathrm{y}=\mathrm{z}$
$\left(G_{2}\right) G(x, x, y)>0$, for all $x, y \varepsilon X$ with $x \neq y$
$\left(G_{3}\right) G(x, x, y) \leq G(x, y, z)$ for all $x, y, z \varepsilon X$ with $z \neq y$.
$\left(G_{4}\right) G(x, y, z)=G(x, z, y)=G(y, z, x)=\ldots$. (Symmetry in all three variables)
$\left(G_{5}\right) G(x, y, z) \leq G(x, a, a)+G(a, y, z)$, for all $x, y, z, a \varepsilon x$ (rectangle inequality )
Then the function $G$ is called a generalized metric or more specifically a $G$ - metric on $X$, and the pair ( $X, G$ ) is called a $G$ - metric space .

Definition 2.2: [15] Let ( $X, G$ ) be a $G$ - metric space, let $\left\{\mathrm{X}_{\mathrm{n}}\right\}$ be a sequence of points of X , we say that $\left\{\mathrm{X}_{\mathrm{n}}\right\}$ converges to a point x in X
lim
if $\lim _{n, m \rightarrow \infty} G\left(x, x_{n}, x_{m}\right)=0$

In other words for $\mathrm{e} \varepsilon>0$ there exists $\mathrm{n}_{0} \varepsilon \mathrm{~N}$ such that $\mathrm{G}\left(\mathrm{x}, \mathrm{x}_{\mathrm{n}}, \mathrm{x}_{\mathrm{m}}\right)<\varepsilon$ for all $\mathrm{n}, \mathrm{m} \geq \mathrm{n}_{0}$ Then x is called the limit of sequence $\left\{\mathrm{X}_{\mathrm{n}}\right\}$.

Definition 2.3: [15] Let ( $X, G$ ) be a G- metric space, a sequence $\left\{x_{n},\right\}$ is called $G$ - Cauchy sequence if for given $\varepsilon>0$, there is $n_{0} \varepsilon N$ such that
$\mathrm{G}\left(\mathrm{x}_{\mathrm{n}}, \mathrm{x}_{\mathrm{m}}, \mathrm{x}_{\mathrm{e}}\right)<\varepsilon$ for all $\mathrm{n}, \mathrm{m}, l \geq \mathrm{n}_{\mathrm{o}}$ that is if. $\mathrm{G}\left(\mathrm{x}_{\mathrm{n}}, \mathrm{x}_{\mathrm{m}}, \mathrm{x}_{\mathrm{e}}\right) \rightarrow 0$ as $\mathrm{n}, \mathrm{m}, l \rightarrow \infty$

[^0]Preposition 2.5: [15] Let (X, G) be a G-metric space, Then, the following are equivalent
(i) $\left\{x_{n}\right\}$ is G- convergent to $x$
(ii) G ( $\left.\mathrm{x}_{\mathrm{n}}, \mathrm{x}_{\mathrm{n}}, \mathrm{x}\right) \rightarrow 0$, as $\mathrm{n} \rightarrow \infty$
(iii) $G\left(x_{n}, x, x,\right) \rightarrow 0$, as $n \rightarrow \infty$
(iv) $G\left(x_{m}, x_{n}, x\right) \rightarrow 0$ as $n, m \rightarrow \infty$

Preposition 2.6: [15] In a G-metric space ( $\mathrm{X}, \mathrm{G}$ ) the following are equivalent
(i) The sequence $\left\{\mathrm{x}_{\mathrm{n}}\right\}$ is G- Cauchy
(ii) For every $\varepsilon>0$, there exists $n_{0} \varepsilon N$ such that $G\left(x_{n}, x_{m}, x_{m}\right)<\varepsilon$ for all $n, m \geq n_{0}$.

Definition 2.7: [16] Let $\phi$ denote the set of alternating distance functions $\phi:[0, \phi[\rightarrow[0, \infty$ [which satisfies following conditions
(i) $\phi$ is strictly increasing
(ii) $\phi$ is upper semi continuous from the right.
(iii) $\sum_{n=0}^{\infty} \phi(t)<\infty$ for all $t>0$
(iv) $\phi(t)=0 \Leftrightarrow t=0$

## MAIN RESULT

Let $\mathrm{f}, \mathrm{g}, \mathrm{h}, \mathrm{r}, \mathrm{s}$, and t be self mappings of a complete G -metric space ( $\mathrm{X}, \mathrm{G}$ ) and
(i) $f(X) \subseteq t(X), g(X) \subseteq s(X), h(X) \subseteq r(X)$ and $f(X)$ or $g(X)$ or $h(X)$ is a closed subset of $X$.
(ii) $G(f x, g y, h z) \leq \phi\{\max \{G(g y, f x, r x), G(h z, g y, t y), G(f x, s z, h z), \alpha G(f x, r x, g y)+\gamma G(s z, f x, r x), \beta G$ (gy, ty, hz) $+\delta \mathrm{G}(\mathrm{fx}, \mathrm{gy}, \mathrm{ty})\}\}$ where $\alpha, \beta, \gamma, \delta, \geq 0, \alpha+\beta+\gamma+\delta<1 / 2$
(iii) $\phi: \mathrm{R}^{+} \rightarrow \mathrm{R}^{+}$is increasing function such that $\phi$ (a) $<\mathrm{a}$ for all $\mathrm{a}>0$ and $\sum \phi$ (a) $<\infty$
(iv) The pairs ( $\mathrm{f}, \mathrm{r}$ ), ( $\mathrm{g}, \mathrm{t}$ ) and ( $\mathrm{h}, \mathrm{s}$ ) are weakly compatible pairs of mappings. Then the mappings $\mathrm{f}, \mathrm{g}, \mathrm{h}, \mathrm{r}, \mathrm{s}$ and t have a unique common fixed point.

Proof: Let $x_{0} \in X$ be an arbitrary point. Then from (i) there exists $x_{1}, x_{2}, x_{3} \in X$ such that $f x_{0}=t x_{1}=y_{0}, g x_{1}=s x_{2}=y_{1}$ and $\mathrm{hx}_{2}=\mathrm{rx}_{3}=\mathrm{y}_{2}$ inductively we define a sequence $\left\{\mathrm{y}_{\mathrm{n}}\right\}$ in X such that $\mathrm{fx}_{3 \mathrm{n}}=\mathrm{tx}_{3 \mathrm{n}+1}=\mathrm{y}_{3 \mathrm{n}}, \mathrm{gx}_{3 \mathrm{n}+1}=s \mathrm{x}_{3 \mathrm{n}+2+}=\mathrm{y}_{3 \mathrm{n}+1}$ and $h x_{3 n+2}=r x_{3 n+3}=y_{3 n+2}$ for $n=0,1,2 \ldots$.

We now prove that $\left\{y_{n}\right\}$ is a Cauchy sequence and for this we define
$d_{m}=G\left(y_{m}, y_{m+1}, y_{m+2}\right)$. so we have.
$d_{3 n}=G\left(y_{3 n}, y_{3 n+1}, y_{3 n+2}\right)$
$=G\left(\mathrm{fx}_{3 \mathrm{n}}, \mathrm{gx}_{3 \mathrm{n}+1}, \mathrm{hx}_{3 \mathrm{n}+2}\right)$
$\leq \phi\left\{\max \left\{G\left(\mathrm{gx}_{3 n+1}, \mathrm{fx}_{3 \mathrm{n}}, \mathrm{rx}_{3 \mathrm{n}}\right), \mathrm{G}\left(\mathrm{hx}_{3 \mathrm{n}+2}, \mathrm{gx}_{3 \mathrm{n}+1}, \mathrm{tx}_{3 \mathrm{n}+1}\right), \mathrm{G}\left(\mathrm{fx}_{3 \mathrm{n}}, \mathrm{sx}_{3 \mathrm{n}+2}, \mathrm{hx} \mathrm{x}_{3 \mathrm{n}+2}\right)\right.\right.$,
$\left.\left.\alpha G\left(f^{n n}, r x_{3 n}, g x_{3 n+1}\right),+\gamma G\left(s x_{3 n+2}, f x_{3 n}, r x_{3 n}\right), \beta G\left(g x_{3 n+1}, t x_{3 n+1}, h x_{3 n+2}\right)+\delta G\left(f_{3 n}, g x_{3 n+1}, t x_{3 n+1}\right)\right\}\right\}$
$\leq \phi\left\{\max \left\{G\left(y_{3 n+1}, y_{3 n}, y_{3 n-1}\right), G\left(y_{3 n+2}, y_{3 n+1}, y_{3 n}\right), G\left(y_{3 n}, y_{3 n+1}, y_{3 n+2}\right), \alpha G\left(y_{3 n}, y_{3 n-1}, y_{3 n+1}\right)\right.\right.$,
$\left.\left.+\gamma G\left(y_{3 n+1}, y_{3 n}, y_{3 n-1}\right), \beta G\left(y_{3 n+1}, y_{3 n}, y_{3 n+2}\right)+\delta G\left(y_{3 n}, y_{3 n+1}, y_{3 n}\right)\right\}\right\}$
$\leq \phi\left\{\max \left\{\mathrm{d}_{3 \mathrm{n}-1}, \mathrm{~d}_{3 \mathrm{n}}, \mathrm{d}_{3 \mathrm{n}}, \alpha \mathrm{d}_{3 \mathrm{n}-1}+\gamma \mathrm{d}_{3 \mathrm{n}-1,1} \beta \mathrm{~d}_{3 \mathrm{n}}+\delta \mathrm{d}_{3 \mathrm{n}}\right\}\right.$ as $\mathrm{G}(\mathrm{a}, \mathrm{a}, \mathrm{x}) \leq \mathrm{G}(\mathrm{x}, \mathrm{y}, \mathrm{z})$
$\leq \phi\left\{\max \left\{\mathrm{d}_{3 n-1},(\gamma+\alpha) \mathrm{d}_{3 \mathrm{n}-1},(\beta+\delta) \mathrm{d}_{3 \mathrm{n}}\right\}\right.$
From the above inequality we have following cases
Case-I: If $\max =\mathrm{d}_{3 n-1}$ then from the inequality

$$
\mathrm{d}_{3 \mathrm{n}} \leq \phi\left\{\mathrm{d}_{3 \mathrm{n}-1}\right\} \leq \mathrm{d}_{3 \mathrm{n}-1} \text { as } \phi(\mathrm{a})<\text { a for all } \mathrm{a}>0 .
$$

Case-II: $\mathrm{d}_{3 \mathrm{n}} \leq \phi\left\{\mathrm{d}_{3 \mathrm{n}}\right\}<\mathrm{d}_{3 \mathrm{n}}$ which is a contradiction.
Case-III: If max $=(\alpha+\gamma) d_{3 n-1}$ then from the inequality

$$
\begin{aligned}
& \mathrm{d}_{3 \mathrm{n}} \leq \phi\left\{(\alpha+\gamma) \mathrm{d}_{3 \mathrm{n}-1}\right\}<(\alpha+\gamma) \mathrm{d}_{3 \mathrm{n}-1} \\
& \mathrm{~d}_{3 \mathrm{n}}<\mathrm{d}_{3 \mathrm{n}-1}
\end{aligned}
$$

Case-IV: If max $=(\beta+\delta) d_{3 n}$, then from the inequality we have
$\mathrm{d}_{3 \mathrm{n}} \leq \phi\left\{(\beta+\delta) \mathrm{d}_{3 \mathrm{n}}\right\}<(\beta+\delta) \mathrm{d}_{3 \mathrm{n}}$
$d_{3 n}<d_{3 n}$ which is a contradiction. Hence in either case we infer that $d_{3 n} \leq d_{3 n-1}$.
Consider,

We have following cases
Case-I: max $=\mathrm{d}_{3 \mathrm{n}}$ then from above inequality $\mathrm{d}_{3 \mathrm{n}+1} \leq \phi\left(\mathrm{d}_{3 \mathrm{n}}\right)<\mathrm{d}_{3 \mathrm{n}}$ as $\phi(\mathrm{a})<$ a for all $\mathrm{a}>0$
Case-II: $\max =d_{3 n+1}$ then we have,$d_{3 n+1} \leq \phi\left(d_{3 n+1}\right)<d_{3 n+1}$ which is a contradiction.
Case-III: $\max =(\alpha+\gamma) \mathrm{d}_{3 \mathrm{n}}$ then we have .
$\mathrm{d}_{3 \mathrm{n}+1} \leq \phi\left\{(\alpha+\gamma) \mathrm{d}_{3 \mathrm{n}}\right\}<(\alpha+\gamma) \mathrm{d}_{3 \mathrm{n}}$, as $\alpha+\beta+\gamma+\delta<1 / 2$ we have $\mathrm{d}_{3 \mathrm{n}+1} \leq \mathrm{d}_{3 \mathrm{n}}$
Case-IV: $\max =(\beta+\delta) \mathrm{d}_{3 \mathrm{n}+1}$ then from the inequality.
$\left.d_{3 n+1} \leq \phi(\beta+\delta) d_{3 n+1}\right\}<(\beta+\delta) d_{3 n+1}$, as $\alpha+\beta+\gamma+\delta<1 / 2, d_{3 n+1}<d_{3 n+1}$ is a contradiction
Hence in either case we have $\mathrm{d}_{3 \mathrm{n}+1} \leq \mathrm{d}_{3 \mathrm{n}}$ Now consider.
$d_{3 n+2}=G\left(y_{3 n+2}, y_{3 n+3}, y_{3 n+4}\right)$

$$
\leq G\left(f x_{3 n+2}, g x_{3 n+3}, h x_{3 n+4}\right)
$$

$$
\leq \phi\left\{\operatorname { m a x } \left\{G\left(g_{3 n+3}, f x_{3 n+2}, r x_{3 n+2}\right), G\left(h x_{3 n+4}, g x_{3 n+3}, t x_{3 n+3}\right), G\left(f x_{3 n+2}, s x_{3 n+4}, h x_{3 n+4}\right),\right.\right.
$$

$$
\left.\left.\alpha G\left(\mathrm{fx}_{3 n+2}, \mathrm{rx}_{3 n+2}, \mathrm{gx}_{3 n+3},\right)+\gamma G\left(\mathrm{sx}_{3 n+4}, \mathrm{fx}_{3 n+2}, \mathrm{rx}_{3 n+2}\right), \beta \mathrm{G}\left(\mathrm{gx}_{3 n+3}, \mathrm{tx}_{3 n+3}, \mathrm{hx}_{3 n+4}\right)+\delta G\left(\mathrm{fx}_{3 n+2}, \mathrm{gx}_{3 n+3}, \mathrm{tx}_{3 n+3}\right)\right\}\right\}
$$

$\leq \phi\left\{\max \left\{G\left(y_{3 n+3}, y_{3 n+2}, y_{3 n+1}\right), G\left(y_{3 n+4}, y_{3 n+3}, y_{3 n+2}\right), G\left(y_{3 n+2}, y_{3 n+3}, y_{3 n+4}\right), \alpha G\left(y_{3 n+2}, y_{3 n+1}, y_{3 n+3}\right)\right.\right.$

$$
\left.\left.+\gamma G\left(y_{3 n+3}, y_{3 n+2}, y_{3 n+1}\right), \beta G\left(y_{3 n+3}, y_{3 n+2}, y_{3 n+4}\right)+\delta G\left(y_{3 n+2}, y_{3 n+3}, y_{3 n+2}\right)\right\}\right\}
$$

$\leq \phi\left\{\max \left\{\mathrm{d}_{3 \mathrm{n}+1}, \mathrm{~d}_{3 \mathrm{n}+2}, \mathrm{~d}_{3 \mathrm{n}+2}, \alpha \mathrm{~d}_{3 \mathrm{n}+1},+\gamma \mathrm{d}_{3 \mathrm{n}+1}, \beta \mathrm{~d}_{3 \mathrm{n}+2}+\delta \mathrm{d}_{3 \mathrm{n}+2}\right\}\right\}$
$\leq \phi\left\{\max \left\{\mathrm{d}_{3 \mathrm{n}+1}, \mathrm{~d}_{3 \mathrm{n}+2},(\alpha+\gamma) \mathrm{d}_{3 \mathrm{n}+1},(\beta+\delta) \mathrm{d}_{3 \mathrm{n}+2}\right\}\right\}$
We have following cases
Case-I: When max $=\mathrm{d}_{3 \mathrm{n}+1}$, then from the inequality we have, $\mathrm{d}_{3 \mathrm{n}+2} \leq \phi\left(\mathrm{d}_{3 \mathrm{n}+1}\right)<\mathrm{d}_{3 \mathrm{n}+1}$
Case-II: max $=d_{3 n+2}$, then $d_{3 n+2} \leq \phi\left(d_{3 n+2}\right)<d_{3 n+2}$, which is a contradiction
Case-III: $\max =(\alpha+\gamma) d_{3 n+1}$ then

$$
\mathrm{d}_{3 n+2} \leq \phi\left\{(\alpha+\delta) d_{3 n+1}\right\}<(\alpha+\delta) d_{3 n+1} \text {, as } \alpha+\beta+\delta+\gamma<1 / 2 \text { we have, } d_{3 n+2} \leq d_{3 n+1}
$$

$$
\begin{aligned}
& d_{3 n+1}=G\left(y_{n+1}, y_{n+2}, y_{n+3},\right) \\
& \leq G\left(\mathrm{fx}_{3 \mathrm{n}+1}, \mathrm{gx}_{3 \mathrm{n}+2}, \mathrm{hx}_{3 \mathrm{n}+3},\right) \\
& \leq \phi\left\{\operatorname { m a x } \left\{G\left(\mathrm{gx}_{3 n+2}, \mathrm{fx}_{3 n+1}, \mathrm{rx}_{3 n+1}\right), \mathrm{G}\left(\mathrm{hx}_{3 n+3}, \mathrm{gx}_{3 n+2}, \mathrm{tx}_{3 n+2}\right), \mathrm{G}\left(\mathrm{fx}_{3 n+1}, \mathrm{sx}_{3 n+3}, h x_{3 n+3}\right),\right.\right. \\
& \left.\left.\alpha G\left(f x_{3 n+1}, r x_{3 n+1}, g x_{3 n+2}\right)+\gamma G\left(s x_{3 n+3}, f x_{3 n+1}, r x_{3 n+1}\right), \beta G\left(g x_{3 n+2}, t x_{3 n+2}, h x_{3 n+3}\right)+\delta G\left(f_{3 n+1}, g x_{3 n+2}, t x_{3 n+2}\right)\right\}\right\} \\
& \leq \phi\left\{\operatorname { m a x } \left\{G\left(y_{3 n+2}, y_{3 n+1}, y_{3 n}\right), G\left(y_{3 n+3}, y_{3 n+2}, y_{3 n+1}\right), G\left(y_{3 n+1}, y_{3 n+2}, y_{3 n+3}\right), \alpha G\left(y_{3 n+1}, y_{3 n}, y_{3 n+2}\right)\right.\right. \\
& \left.\left.+\gamma G\left(y_{3 n+2}, y_{3 n+1}, y_{3 n}\right), \beta G\left(y_{3 n+2}, y_{3 n+1}, y_{3 n+3}\right)+\delta G\left(y_{3 n+1}, y_{3 n+2}, y_{3 n+1}\right)\right\}\right\} \\
& \leq \phi\left\{\max \left\{\mathrm{d}_{3 \mathrm{n}}, \mathrm{~d}_{3 \mathrm{n}+1}, \mathrm{~d}_{3 \mathrm{n}+1}, \alpha \mathrm{~d}_{3 \mathrm{n}},+\gamma \mathrm{d}_{3 \mathrm{n}}, \beta \mathrm{~d}_{3 \mathrm{n}+1+} \delta \mathrm{d}_{3 \mathrm{n}+1}\right\}\right\} \text { as } \mathrm{G}(\mathrm{a}, \mathrm{a}, \mathrm{x}) \leq \mathrm{G}(\mathrm{x}, \mathrm{y}, \mathrm{z}) \\
& \leq \phi\left\{\max \left\{d_{3 n}, d_{3 n+1},(\alpha+\gamma) d_{3 n},(\beta+\delta) d_{3 n+1}\right\}\right.
\end{aligned}
$$

Case-IV: $\max =(\beta+\delta) \mathrm{d}_{3 \mathrm{n}+2}$
$\mathrm{d}_{3 \mathrm{n}+2} \leq \phi\left\{(\beta+\delta) \mathrm{d}_{3 \mathrm{n}+2}\right\}<(\beta+\delta) \mathrm{d}_{3 \mathrm{n}+2}$. Which is a contradiction as $\alpha+\beta+\gamma+\delta<1 / 2$. Hence in either cases $d_{3 n+2} \leq d_{3 n+1}$. From above cases we can say that $d_{n} \leq d_{n-1}$ for every $n \in N$. So, we get $d_{n} \leq \mathrm{qd}_{n-1}$ where $\mathrm{q}=\alpha+\beta+\gamma+\delta$ i.e. $\mathrm{d}_{\mathrm{n}}=\mathrm{G}\left(\mathrm{y}_{\mathrm{n}}, \mathrm{y}_{\mathrm{n}+1}, \mathrm{y}_{\mathrm{n}+2}\right) \leq \mathrm{q} G\left(\mathrm{y}_{\mathrm{n}-1}, \mathrm{y}_{\mathrm{n}}, \mathrm{y}_{\mathrm{n}+1}\right) \leq \mathrm{q}^{\mathrm{n}} \mathrm{G}\left(\mathrm{y}_{0}, \mathrm{y}_{1}, \mathrm{y}_{2}\right)$.

Also we have $G(x, x, y) \leq G(x, y, z)$, hence we get $G\left(y_{n}, y_{n}, y_{n+1}\right) \leq q^{n} G\left(y_{0}, y_{1}, y_{2}\right)$ and

$$
G\left(y_{n}, y_{n}, y_{m}\right) \leq G\left(y_{n}, y_{n}, y_{n+1}\right)+G\left(y_{n+1}, y_{n+1}, y_{n+2}\right)+----+-----+G\left(y_{m-1}, y_{m-1}, y_{m}\right)
$$

$$
\leq q^{n} G\left(y_{0}, y_{1}, y_{2}\right)+q^{n+1} G\left(y_{0}, y_{1}, y_{2}\right)+\cdots+--q^{n-1} G\left(y_{0}, y_{1}, y_{2}\right)
$$

$$
\leq\left(\frac{q^{n}-q^{m}}{1-q}\right) G\left(\mathrm{y}_{0}, \mathrm{y}_{1}, \mathrm{y}_{2}\right) \leq\left(\frac{q^{n}}{1-q}\right) G\left(\mathrm{y}_{0}, \mathrm{y}_{1}, \mathrm{y}_{2}\right) \rightarrow 0 \text { as } n \rightarrow \infty
$$

So, the sequence $\left\{y_{n}\right\}$ is a Cauchy sequence in $X$ and as $X$ is complete $\left\{y_{n}\right\}$ will converge to $y$ in $X$ i.e. $\lim _{n \rightarrow \infty} y_{n}=y$, $\lim _{n \rightarrow \infty} \mathrm{fx}_{3 \mathrm{n}}=\lim _{n \rightarrow \infty} \mathrm{gx}_{3 n+1}=\lim _{n \rightarrow \infty} \mathrm{hx}_{3 n+2}=\quad \lim _{n \rightarrow \infty} \mathrm{tx}_{3 n+1}=\lim _{n \rightarrow \infty} \mathrm{Sx}_{3 n+2}$
$=\lim _{n \rightarrow \infty} r_{3 n+3}=y$. Let $h(X)$ is a closed subset of $r(X)$. Then there exists $u \in X$ such that $r u=y$ Now consider
$G\left(f u, \mathrm{gx}_{3 n+1}, h x_{3 n+2}\right) \leq \phi\left\{\max \left\{G\left(\mathrm{gx}_{3 n+1}, f u, r u\right), G\left(h x_{3 n+2}, \mathrm{gx}_{3 n+1}, \mathrm{tx}_{3 n+1}\right), G\left(f u, \mathrm{sx}_{3 n+2}, h x_{3 n+2}\right)\right.\right.$,
$\left.\left.\alpha G\left(f u, r u, g x_{3 n+1}\right)+\gamma G\left(s x_{3 n+2}, f u, r u\right), \beta G\left(\mathrm{gx}_{3 n+1}, t x_{3 n+1}, h x_{3 n+2}\right)+\delta G\left(f u, g x_{3 n+1}, h x_{3 n+1}\right)\right\}\right\}$
$\leq \phi\{\max \{G(y, f u, r u), G(y, y, y), G(f u, y, y), \alpha G(f u, r u, y)+\gamma G(y, f u, r u)$,
$\beta G(y, y, y)+\delta G(f u, y, y)\}\}$
$\leq \phi\{\max \{G(y, f u, y), G(y, y, y), G(f u, y, y), \alpha G(f u, y, y)+\gamma G(y, f u, y)$, $\beta G(y, y, y)+\delta G(f u, y, y)\}\}$ $\leq \phi\{\max \{G(f u, y, y),(\alpha+\gamma) G(f u, y, y), \delta G(f u, y, y)\}$

We have following cases
Case-I: $\max =\mathrm{G}(\mathrm{fu}, \mathrm{y}, \mathrm{y})$ then from above inequality we have.
$\mathrm{G}(\mathrm{fu}, \mathrm{y}, \mathrm{y}) \leq \phi\{\mathrm{G}(\mathrm{fu}, \mathrm{y}, \mathrm{y})\}<\mathrm{G}(\mathrm{fu}, \mathrm{y}, \mathrm{y})$, which is a contraction.
Case-II: $\max =(\alpha+\gamma) G(f u, y, y)$ then from above inequality we have.
$G(f u, y, y) \leq \phi\{(\alpha+\gamma) G(f u, y, y)\}<(\alpha+\gamma) G(f u, y, y) \leq G(f u, y, y)$. This implies $G(f u, y, y)=0, f u=y$.
Case-III: $\max =\delta \mathrm{G}(\mathrm{fu}, \mathrm{y}, \mathrm{y})$ then from above inequality we have
$G(f u, y, y) \leq \phi\{\delta G(f u, y, y)\}<\delta G(f u, y, y) \leq G(f u, y, y)$. This implies $G(f u, y, y)=0, f u=y . A s r u=y$ we have $f u=r u=y$. As the pair $(f, r)$ is weakly compatible we have $f r u=r f u$ hence $f y=r y$. Now we prove that $f y=y$.
$G\left(f y, g x_{3 n+1}, h x_{3 n+2}\right) \leq \phi\left\{\max \left\{G\left(g x_{3 n+1}, f y, r y\right), G\left(h x_{3 n+2}, g x_{3 n+1}, t x_{3 n+1}\right), G\left(f y, s x_{3 n+2}, h x_{3 n+2}\right)\right.\right.$, $\left.\left.\alpha G\left(f y, r y, g x_{3 n+1}\right)+\gamma G\left(s x_{3 n+2}, f y, r y\right), \beta G\left(g x_{3 n+1}, t x_{3 n+1}, h x_{3 n+2}\right)+\delta G\left(f y, g x_{3 n+1}, t x_{3 n+1}\right)\right\}\right\}$
$\leq \phi\{\max \{G(y, f y, r y), G(y, y, y), G(f y, y, y), \alpha G(f y, r y, y)$
$+\gamma G(y, f y, r y), \beta G(y, y, y)+\delta G(f y, y, y)\}\}$
$\leq \phi\{\max \{G(y, f y, f y), G(f y, y, y), \alpha G(f y, f y, y)+\gamma G(f y, f y, y), \delta G(f y, y, y)\}$
$\leq \phi\{\max \{2 \mathrm{G}(\mathrm{y}, \mathrm{fy}, \mathrm{y}), \mathrm{G}(\mathrm{fy}, \mathrm{y}, \mathrm{y}),(2 \alpha+2 \gamma) \mathrm{G}(\mathrm{y}, \mathrm{fy}, \mathrm{y}), \delta \mathrm{G}(\mathrm{fy}, \mathrm{y}, \mathrm{y})\}$
$\leq \phi\{\max \{2 G(y, f y, y),(2 \alpha+2 \gamma) G(y, f y, y), \delta G(f y, y, y)\}$
We have following cases
Case-I: $\max =2 \mathrm{G}(\mathrm{y}, \mathrm{fy}, \mathrm{y})$ then from above inequality we get. $\mathrm{G}(\mathrm{y}, \mathrm{fy}, \mathrm{y})=0 \mathrm{i}, \mathrm{e} f \mathrm{f}=\mathrm{y}$.

Case-II: $\max =\delta \mathrm{G}(\mathrm{fy}, \mathrm{y}, \mathrm{y})$ then from the equality
$\mathrm{G}(\mathrm{fy}, \mathrm{y}, \mathrm{y}) \leq \phi\{\delta \mathrm{G}(\mathrm{fy}, \mathrm{y}, \mathrm{y})\}<\delta \mathrm{G}$ (fy, $\mathrm{y}, \mathrm{y})$, as $\alpha+\beta+\gamma+\delta<1 / 2$ so we have
$G(f y, y, y)=0$ which implies $f y=y$.
Case-III: $\max =(2 \alpha+2 \gamma) G(f u, y, y)$ then
$G(f u, y, y) \leq \phi\{(2 \alpha+2 \gamma) G(f y, y, y)\}<(2 \alpha+2 \gamma) G(f y, y, y) \leq G(f y, y, y)$ which implies fy $=y$
As $f y=r y=y$, we conclude $f$, $r$ have common fixed point $y$. As $y=f y \in f(X) \subseteq t(X)$ there exists $w$ such that $t w=y$. We shall now prove that $\mathrm{gw}=\mathrm{y}$.
$G\left(y, g w, h x_{3 n+2}\right)=G\left(f y, g w, h x_{3 n+2}\right)$

$$
\begin{aligned}
& \leq \phi\left\{\begin{array}{l}
\max \left\{G(g w, f y, r y), G\left(h x_{3 n+2}, g w, t w\right), G\left(f y, ~ s x_{3 n+2}, h x_{3 n+2}\right), \alpha G(f y, r y, g w)\right. \\
\left.\left.\quad+\gamma G\left(s x_{3 n+2}, f y, r y\right), \beta G\left(g w, t w, h x_{3 n+2}\right)+\delta G(f y, g w, t w)\right\}\right\} \\
\leq \phi\{\max \{G(g w, y, y), G(y, g w, y), G(y, y, y), \alpha G(y, y, g w)+\gamma G(y, y, y), \\
\quad \beta G(g w, y, y)+\delta(y, g w, y)\}\} \\
\leq \phi\{\max \{G(y, g w, y), \alpha G(y, y, g w),(\beta+\delta) G(g w, y, y)\}
\end{array}\right.
\end{aligned}
$$

We have following cases
Case-I: $\max =G(y, g w, y)$ then from the inequality

$$
\mathrm{G}(\mathrm{y}, \mathrm{gw}, \mathrm{y}) \leq \phi\{\mathrm{G}(\mathrm{y}, \mathrm{gw}, \mathrm{y})\}<\mathrm{G}(\mathrm{y}, \mathrm{gw}, \mathrm{y}) \text { which is a contraction. }
$$

Case-II: $\max =\alpha G(y, g w, y)$ then from the inequality
$G(y, g w, y) \leq \phi\{\alpha G(y, g w, y)\}<\alpha G(y, g w, y)$ which implies $G(y, g w, y)=0$ then $g w=y . A s t w=y=g w$ and $(\mathrm{g}, \mathrm{t})$ being weakly compatible we have $\mathrm{gtw}=\mathrm{tgw}$. Then $\mathrm{gy}=\mathrm{ty}$. We now prove $\mathrm{gy}=\mathrm{y}$.

## Consider

$G\left(f y, g y, h x_{3 n+2}\right) \leq \phi\left\{\max \left\{G(g y, f y, r y), G\left(h x_{3 n+2}, g y, t y\right), G\left(f y, s x_{3 n+2}, h x_{3 n+2}\right), \alpha G(f y, r y, g y)\right.\right.$

$$
\left.\left.+\gamma G\left(\mathrm{sx}_{3 \mathrm{n}+2}, \mathrm{fy}, \mathrm{ry}\right), \beta \mathrm{G}\left(\mathrm{gy}, \mathrm{ty}, \mathrm{hx}_{3 \mathrm{n}+2}\right)+\delta \mathrm{G}(\mathrm{fy}, \mathrm{gy}, \mathrm{ty})\right\}\right\}
$$

$\leq \phi\{\max \{G(g y, y, y), G(y, g y, g y), G(y, y, y), \alpha G(y, y, g y)+\gamma G(y, y, y)$, $\beta G(g y, g y, y)+\delta G(y, g y, g y)\}\}$
$\leq \phi\{\max \{G(g y, y, y), 2 G(y, g y, y), \alpha G(y, y, g y),(2 \beta+2 \delta G(y, y, g y)\}$
$\leq \phi\{\max \{2 \mathrm{G}(\mathrm{y}, \mathrm{gy}, \mathrm{y}), \alpha \mathrm{G}(\mathrm{y}, \mathrm{y}, \mathrm{gy}),(2 \beta+2 \delta) \mathrm{G}(\mathrm{y}, \mathrm{y}, \mathrm{gy})\}$
We have following cases
Case-I: $\max =2 \mathrm{G}(\mathrm{y}, \mathrm{gy}, \mathrm{y})$ then from the above inequality.
$G(y, g y, y) \leq \phi\{2 G(y, g y, y)\}<2 G(y, g y, y)$, which implies $G(y, g y, y)=0$ then $g y=y$
Case-II: $\max =\alpha G(y, y, g y)$ then from the inequality we have.
$G(y, g y, y) \leq \phi\{\alpha G(y, y, g y)\}<\alpha G(y, y, g y)$.This implies $G(y, y, g y)=0$.Thus we have $g y=y$.
Case-III: $\max =(2 \beta+2 \delta) G(y, y, g y)$ then from the inequality we have.
$G(y, g y, y) \leq \phi\{(2 \beta+2 \delta) G(y, y, g y)\}<(2 \beta+2 \delta) G(y, y, g y)$. This implies $G(y, y, g y)=0$
So we have $\mathrm{gy}=\mathrm{y}$. Thus in either cases $\mathrm{gy}=\mathrm{y}$ and as $\mathrm{gy}=\mathrm{ty}=\mathrm{y}$ we have y is common fixed point of $\mathrm{g}, \mathrm{t}$.
Since $y=g y \in g(X) \subseteq S(X)$ there exist $v \in X$ such that $s v=y$. We now prove that $h v=y$.
G ( $\mathrm{y}, \mathrm{y}, \mathrm{hv}$ ) = G (fy, gy, hv)
$\leq \phi\{\max \{G(g y, f y, r y), G(h v, ~ g y, ~ t y), G(f y, ~ s v, ~ h v), ~ \alpha G(f y, ~ r y, ~ g y) ~$
$+\gamma \mathrm{G}$ (sv, fy, ry), $\beta$ G (gy, ty, hv) $+\delta \mathrm{G}$ (fy, gy, ty) $\}\}$
$\leq \phi\{\max \{G(y, y, y), G(h v, y, y), G(y, y, h v), \alpha G(y, y, y)$
$+\gamma G(y, y, y), \beta G(y, y, h v)+\delta G(y, y, y)\}\}$
$\leq \phi\{\max \{\mathrm{G}(\mathrm{hv}, \mathrm{y}, \mathrm{y}), \beta \mathrm{G}(\mathrm{y}, \mathrm{y}, \mathrm{hv})\}$

We have following cases
Case-I: $\max =\mathrm{G}(\mathrm{y}, \mathrm{y}, \mathrm{hv})$ then from the inequality above we have.
$\mathrm{G}(\mathrm{y}, \mathrm{y}, \mathrm{hv}) \leq \phi\{\mathrm{G}(\mathrm{y}, \mathrm{y}, \mathrm{hv})\}<\mathrm{G}(\mathrm{y}, \mathrm{y}, \mathrm{hv})$, which implies $\mathrm{G}(\mathrm{y}, \mathrm{y}, \mathrm{hv})=0$ then $\mathrm{hv}=\mathrm{y}$
Case-II: $\max =\beta \mathrm{G}(\mathrm{y}, \mathrm{y}, \mathrm{hv})$ then from the inequality we have.
$\mathrm{G}(\mathrm{y}, \mathrm{y}, \mathrm{hv}) \leq \phi\{\beta \mathrm{G}(\mathrm{y}, \mathrm{y}, \mathrm{hv})\}<\beta \mathrm{G}(\mathrm{y}, \mathrm{y}, \mathrm{hv})$, which implies $\mathrm{hv}=\mathrm{y}$. Thus in either cases $\mathrm{hv}=\mathrm{y}$. As sv = y so we have $\mathrm{sv}=\mathrm{hv}=\mathrm{y}$. Since ( $\mathrm{h}, \mathrm{s}$ ) are weakly compatible so $\mathrm{hsv}=\mathrm{shv}$ then $\mathrm{hy}=\mathrm{sy}$. We now prove that hy $=\mathrm{y}$.

Consider

$$
\begin{aligned}
& G(y, y, h y)=G(f y, g y, h y) \\
& \leq \phi\{\max \{G(g y, f y, r y), G(h v, ~ g y, ~ t y), G(f y, ~ s y, ~ h y), ~ \alpha G(f y, ~ r y, ~ g y) ~ \\
& +\gamma \text { G (sy, fy, ry), } \beta \text { G (gy, ty, hy) }+\delta \text { G (fy, gy, ty) }\}\} \\
& \leq \phi\{\max \{G(y, y, y), G(h y, y, y), G(y, h y, h y), \alpha G(y, y, y)+\gamma G(h y, y, y), \\
& \beta G(y, y, h y)+\delta G(y, y, y)\}\} \\
& \leq \phi\{\max \{\mathrm{G} \text { hy, } \mathrm{y}, \mathrm{y}), \gamma \mathrm{G}(\mathrm{hy}, \mathrm{y}, \mathrm{y}), \beta \mathrm{G}(\mathrm{y}, \mathrm{y}, \mathrm{hy})
\end{aligned}
$$

We have following cases
Case-I: $\max =\mathrm{G}(\mathrm{hy}, \mathrm{y}, \mathrm{y})$ then from the inequality we have.
$\mathrm{G}(\mathrm{hy}, \mathrm{y}, \mathrm{y}) \leq \phi\{\mathrm{G}(\mathrm{hy}, \mathrm{y}, \mathrm{y})\}<\mathrm{G}$ (hy, $\mathrm{y}, \mathrm{y}$ ) which is a contradiction .
Case-II: $\max =\gamma \mathrm{G}(\mathrm{hy}, \mathrm{y}, \mathrm{y})$ then from the inequality we have.
G (hy, y, y) $\leq \phi\{\gamma \mathrm{G}$ (hy, y, y) $\}<\gamma$ G (hy, y, y), hence G (hy, y, y) $=0$ which gives hy $=\mathrm{y}$.
Case-III: $\max =\beta \mathrm{G}(\mathrm{hy}, \mathrm{y}, \mathrm{y})$ then from the inequality we have. $\mathrm{G}(\mathrm{hy}, \mathrm{y}, \mathrm{y}) \leq \phi\{\beta \mathrm{G}(\mathrm{hy}, \mathrm{y}, \mathrm{y})\}<\beta \mathrm{G}$ (hy, $\mathrm{y}, \mathrm{y})$, which implies G (hy, y, y) $=0$ which gives hy $=\mathrm{y}$.

Thus in either cases $h y=y$. As $s y=h y=y$ therefore $y$ is common fixed point of $s$ and $h$. Thus $y$ is common fixed point of $\mathrm{f}, \mathrm{r}, \mathrm{s}, \mathrm{t}, \mathrm{h}, \mathrm{g}$. We shall now prove that the fixed point is unique. Let $\mathrm{y}^{\prime}$ be another fixed point of $\mathrm{f}, \mathrm{r}, \mathrm{g}, \mathrm{t}, \mathrm{s}, \mathrm{h}$. Then

G (y, y, hy') = G (fy , gy, hy')

$$
\begin{aligned}
\leq \phi & \{\max \{G(g y, f y, r y), G(h y ', g y, t y), G(f y, \text { hy', sy'), } \alpha G(f y, r y, ~ g y) \\
& +\gamma G(s y ', f y, r y), \beta G(g y, t y, h y ')+\delta G(f y, g y, t y)\}\} \\
\leq \phi & \left\{\max \left\{G(y, y, y), G\left(y^{\prime}, y, y\right), G\left(y, y^{\prime}, y^{\prime}\right), \alpha G(y, y, y)+\gamma G\left(y^{\prime}, y, y\right), \beta G\left(y, y, y^{\prime}\right)+\delta G(y, y, y)\right\}\right\} \\
\leq & \phi\left\{\max \left\{G\left(y^{\prime}, y, y\right), 2 G\left(y, y, y^{\prime}\right), \gamma G\left(y, y^{\prime}, y\right), \beta G\left(y, y, y^{\prime}\right)\right\}\right. \\
\leq & \left\{\max \left\{2 G\left(y, y, y^{\prime}\right), \gamma G\left(y, y, y^{\prime}\right), \beta G\left(y, y, y^{\prime}\right)\right\}\right\}
\end{aligned}
$$

We have following cases
Case-I: $\max =\beta G\left(y, y, y^{\prime}\right)$ then from the inequality we have.
$G\left(y, y, y^{\prime}\right) \leq \phi\left\{\beta G\left(y, y, y^{\prime}\right)\right\}<\beta G\left(y, y, y^{\prime}\right)$, which implies $G\left(y, y, y^{\prime}\right)=0$ then $y=y^{\prime}$
Case-II: $\max =2 \mathrm{G}\left(\mathrm{y}, \mathrm{y}, \mathrm{y}^{\prime}\right)$ then from the inequality we have.
$\mathrm{G}\left(\mathrm{y}, \mathrm{y}, \mathrm{y}^{\prime}\right)=\phi\left\{2 \mathrm{G}\left(\mathrm{y}, \mathrm{y}, \mathrm{y}^{\prime}\right)\right\}<2 \mathrm{G}\left(\mathrm{y}, \mathrm{y}, \mathrm{y}^{\prime}\right)$, which implies $\mathrm{G}\left(\mathrm{y}, \mathrm{y}, \mathrm{y}^{\prime}\right)=0$ as Therefore $\mathrm{y}=\mathrm{y}^{\prime}$
Case-III: $\max =\gamma \mathrm{G}\left(\mathrm{y}, \mathrm{y}, \mathrm{y}^{\prime}\right)$ then from the inequality we have.
$\mathrm{G}\left(\mathrm{y}, \mathrm{y}, \mathrm{y}^{\prime}\right)=\phi\left\{\gamma \mathrm{G}\left(\mathrm{y}, \mathrm{y}, \mathrm{y}^{\prime}\right)\right\}<\gamma \mathrm{G}\left(\mathrm{y}, \mathrm{y}, \mathrm{y}^{\prime}\right)$, which implies $\mathrm{G}\left(\mathrm{y}, \mathrm{y}, \mathrm{y}^{\prime}\right)=0$ as Therefore $\mathrm{y}=\mathrm{y}{ }^{\prime}$
Thus the mappings $\mathrm{f}, \mathrm{r}, \mathrm{g}, \mathrm{t}, \mathrm{h}$, s have unique common fixed point.
